Abstract

**Background:** The nutritional status of pregnant women are affected by daily nutritional intake. Daily nutritional intake during pregnancy depends on total macronutrient intake and micronutrient intake. The aim of the study is to describe daily nutritional intake from pregnant women in Temanggung, Central Java, Indonesia.

**Method:** This study was conducted from September – December 2016 in Temanggung. This was a cross-sectional study and the respondents were recruited using purposive sampling technique. Total sample of this study were 60 pregnant women. Intakes of macronutrients (Energy, and Protein), and micronutrients were calculated based on Food Frequency Questionnaire (FFQ) Semi Quantitative and using Nutrisoft software, Demographic data were obtained by interviewing.

**Results:** Of the total 60 pregnant women, 40 (66.7\%) were unemployed. The majority of educational level of the respondents (48.3\%) were Junior High School. The mean gestational age were 6.70 ± 1.109 months. The mean intake of energy in 60 pregnant women was 2153.9833 ± 369 kcal

**Conclusion:** The majority of pregnant women in this study have adequate intake of both macro and micronutrient besides iron and folic acid.

**Keywords:** Intake, Pregnant, Nutrition, Temanggung

Background

Indonesian Health Demographic Survey (IHDS) in 2012 shows that Maternal Mortality Rate (MMR) is increasing significantly from 228 to 259 deaths per 100,000 live births.\(^1\) Infant Mortality Rate (IMR) is 32 per 1,000 live births\(^1\). These numbers shows that mother and child health should be considered. There are many reasons why the MMR is increasing. Pregnant women might having complications during and following pregnancy and childbirth. The major complications in maternal deaths are severe bleeding, infections, high blood pressure during pregnancy (pre-eclampsia and eclampsia),
complication from delivery, unsafe abortion and maternal nutritional status.\textsuperscript{2}

The nutritional status of pregnant women are affected by daily nutritional intake.\textsuperscript{3} Nutrient intake during pregnancy is different with nutrient intake before pregnancy. Daily nutritional intake during pregnancy depends on total macronutrient intake and micronutrient intake such as iron, folic acid, cobalamin (B\textsubscript{12}), vitamin D, iodium, calcium, vitamin A and zinc.\textsuperscript{4,5} Based on Indonesian Recommended Daily Intake (RDI) in 2013, pregnant woman need an additional 300 kcal/day of energy, additional 20 gr/day of Protein, 10 gr/day of fat and 40 gr/day of carbohydrate during pregnancy.\textsuperscript{6}

During pregnancy, an additional of 80,000 kcal for 280 days are required. On first trimester energy requirement is increasing minimally. On the second and third trimester, it increase gradually until the end of pregnancy. Energy is use for fetal growth, development of maternal and fetal tissues, and accumulation of fat.\textsuperscript{7}

Protein requirement is developing about 68\%. Total protein requirement during pregnancy is 925 gr in maternal tissues, placenta and fetus.\textsuperscript{8} Protein in pregnant woman is use for fetal growth, uterine placental growth, and enhance blood volume.\textsuperscript{9} Source of protein is from animal protein and vegetable protein.\textsuperscript{10}

Pregnant women need vitamin A for the health of themselves as well as for the health and development of the fetus. It is because vitamin A is important for cell division, fetal organ and skeletal growth and maturation, maintenance of the immune system to strengthen defences against infection, and development of vision in the fetus as well as maintenance of maternal eye health and night vision.\textsuperscript{11}

Fiber is a nutrient that could not get digested by human tract. It absorbs water and helps bowel movements.\textsuperscript{12} The daily recommended intake of fiber for women age 16-35 is 30-32 gr/day and for pregnant women additional intake of 3 gr/day fiber is needed in first trimester, 4 gr/day in second and third trimester.\textsuperscript{6} Proper fiber intake avoids constipation and hemorrhoids during pregnancy.\textsuperscript{13}

Folic acid requirements are increased in pregnancy because of the rapidly dividing cells in the fetus and elevated urinary losses. During pregnancy, women need additional of 200 mcg folate per day.\textsuperscript{6} Folic acid (FA) has been shown to reduce the risk of neural tube defects (NTD).\textsuperscript{14}

Vitamin B12 maintains normal folate metabolism which is essential for cell multiplication, specifically in the rapidly dividing placental and fetal tissues. Deficiency of Vitamin B12 can affect the pregnancy outcome for both mother and the offspring. When vitamin B12 intake is below the daily recommended intake it will increase the risk of developing preeclampsia, intrauterine growth retardation, and preterm labor.\textsuperscript{15,16} The recommended daily intake of vitamin B12 in women age 16-35 is 2,4 mcg per day with additional intake of 0,2 mcg vitamin B12 per day is needed during pregnancy.\textsuperscript{6}

Calcium is essential for muscle contraction, bone formation, and enzyme and hormone functioning. Calcium absorption increases during pregnancy. WHO
recommend the daily intake of calcium in pregnant women is 1200 mg/day.\textsuperscript{17} 

Women need to have adequate storage of iron to meet the high requirements of this mineral during the pregnancy. The total iron required during pregnancy is about 1000 mg\textsuperscript{18}. Iron deficiency leads to anemia during pregnancy. It is harmful for both woman and child health.\textsuperscript{19} 

Zinc during pregnancy is essential for tissue growth, cell division, fetal growth and development, and also mammary gland function for milk synthesis.\textsuperscript{20} Zinc deficiency in pregnant woman often lead to zinc malabsorption which resulted in fetus with several skin disorders and prone to die young of viral or fungal infections.\textsuperscript{21} Recommended daily intake of zinc in women age 16-35 is 10 mg/day and additional of 2 mg zinc per day is needed during the first trimester, 4 mg/day in second trimester and 10 mg/day during third trimester in pregnant women.\textsuperscript{6} The aim of the study is to describe daily nutritional intake from pregnant women in Temanggung District, Central Java, Indonesia. 

**Methods** 

This study was conducted from September – December 2016 in Temanggung. It is located in Central Java, Indonesia. This was a cross sectional study and the respondents were recruited using purposive sampling technique. 

The population of this study were 114 pregnant women. Inclusion criteria were pregnant women who were at 5-8 months of gestation and agreed to participate in the study. 

Total sample of this study were 60 pregnant women. Intakes of macronutrients (Energy, and Protein), and micronutrients (vitamin A, iron, vitamin B\textsubscript{12}, zinc, calcium, folic acid, fiber) were calculated based on Food Frequency Questionnaire (FFQ) Semi Quantitative and using Nutrisoft software, Demographic data were obtained by interview including level of education, occupation, age, and gestational age. Ethical clearance was approved by the Commision on Health Research Ethics Faculty of Public Health, Diponegoro University Semarang No: 252/EC/FKM/2016. 

**Results** 

Tabel 1 shows that the majority of educational level of the respondents (48,3\%) were Junior High School. It means that educational level of the respondents were low. Of the total 60 pregnant women, 40 (66,7\%) were unemployed while other 20 (33,3\%) were working. The mean age of pregnant women in this study were 26.02 ± 5.637 years old. The mean gestational age were 6.70 ± 1,109 months. Further level of education, maternal occupation, age and gestational age can be seen in table 1. The mean intake of energy in 60 pregnant women was 2153,9833 ± 369 kcal . The details of daily nutritional intakes of both macro and micronutrients are summarized in table 2.

**Discussion**

The study showed that energy intake of pregnant women was adequate compared to the recommended daily intake (RDI) for pregnant women in Indonesia. This results are in line with other study conducted in
Malaysia. Mean energy intake ( > 2189.63 kcal/day) was adequate as compared with the Recommended Nutrient Intake (RNI) for Malaysian pregnant women.\textsuperscript{22} Another study in Pakistan shows different results. Their results point out low energy consumption of mothers in early as well as in late gestation compared to recommended dietary allowance for pregnant mothers in Pakistan.\textsuperscript{23}

Other studies in Thailand indicate that more than half of the women in that study were found to have nutrient intake inadequacy for all macronutrients plus calcium and thiamine. Almost half of the women had a lower iron and niacin intake compared to the Thai RDA.\textsuperscript{24}

Intakes of Protein, fiber, vitamin B\textsubscript{12}, calcium, zinc and vitamin A were also adequate compared to the Indonesian RDI for pregnant women. On the contrary, folic acid and iron consumptions were low while these substance are essential during pregnancy.

Low intake of iron during pregnancy could affect both maternal and infant outcomes. Iron deficiency in pregnant women increases the risk of becoming anemic during pregnancy.\textsuperscript{25} The outcomes of anemic during pregnancy are bleeding during childbirth, increase the risk of low birth weight baby, and even maternal mortality.\textsuperscript{26}

Folic acid is increasing during pregnancy to forms RBC (Red Blood Cells), DNA synthesis, and for development of placenta and fetus.\textsuperscript{27} When the consumption of folic acid in pregnant women is low it could increase the risk of NTD (Neural Tubes Defects) and megaloblastic anemia.\textsuperscript{28}

It is very important for pregnant women to maintain their health and consume high macro and micronutrient food. In this case food that contains folic acid such as orange, carrot, broccoli, spinach, potatoes, liver and also food that contains high iron for examples oysters, beans, spinach, etc should consume more often to prevent anemic during pregnancy.

**Conclusions**

Based on the result, the majority of pregnant women in this study have adequate intake of both macro and micronutrient besides iron and folic acid.

**Acknowledgement**

Our grateful thank to Sugiarti as the head of Tocologist at Puskesmas Bulu, Temanggung, Indonesia and to all the district’s tocologists in Bulu District, Temanggung and also to all of the pregnant women in Bulu District who had been willing to participate in this study.

**Ethics approval and consent**

Ethical clearance was approved by the Commission on Health Research Ethics Faculty of Public Health, Diponegoro University Semarang No: 252/EC/FKM/2016.
